- □ Evaluating Effectiveness

True Misclassification Rate

### **Definition 8 (True Misclassification Rate)**

Let X be a feature space with a finite number of elements. Moreover, let C be a set of classes, let  $y:X\to C$  be a classifier, and let c be the target concept to be learned. Then the true misclassification rate, denoted as  $\mathit{Err}^*(y)$ , is defined as follows:

$$\textit{Err}^*(y) = \frac{|\{\mathbf{x} \in X : y(\mathbf{x}) \neq c(\mathbf{x})\}|}{|X|}$$

True Misclassification Rate

### **Definition 8 (True Misclassification Rate)**

Let X be a feature space with a finite number of elements. Moreover, let C be a set of classes, let  $y:X\to C$  be a classifier, and let c be the target concept to be learned. Then the true misclassification rate, denoted as  $\mathit{Err}^*(y)$ , is defined as follows:

$$\textit{Err}^*(y) = \frac{|\{\mathbf{x} \in X : y(\mathbf{x}) \neq c(\mathbf{x})\}|}{|X|}$$

#### Problem:

 $\Box$  Usually the *total function* c is unknown.

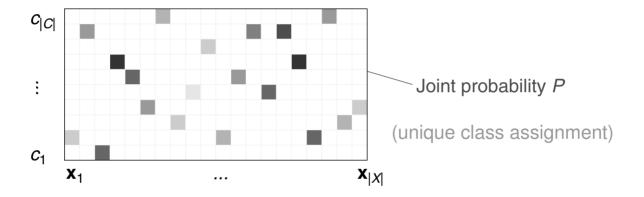

### Solution:

□ Estimation of  $Err^*(y)$  with  $Err(y, D_{ts})$ , i.e., evaluating y on a subset  $D_{ts} \subseteq D$  of carefully chosen examples D. Recall that for the feature vectors in D the target concept c is known.

- Instead of the term "true misclassification rate" we may also use the term "true misclassification error" or simply "true error".
- The English word "rate" can be used to denote both the mathematical concept of a *flow quantity* (a change of a quantity per time unit) as well as the mathematical concept of a *portion*, a *percentage*, or a *ratio*, which has a stationary (= time-independent) semantics. Note that the latter semantics is meant here when talking about the misclassification rate.
- □ Unfortunately, the German word "Rate" is often (mis)used to denote the mathematical concept of a portion, a percentage, or a ratio. Taking a precise mathematical standpoint, the correct German words are "Anteil" or "Quote". I.e., a semantically correct translation of misclassification rate is "Missklassifikationsanteil", and not "Missklassifikationsrate".

True Misclassification Rate: Probabilistic Foundation

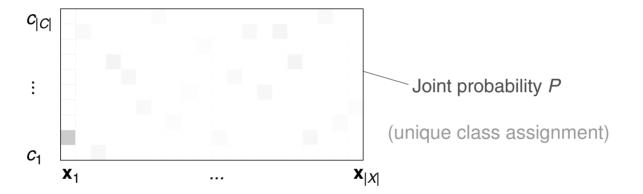

Let X be a feature space, C a set of classes, and P a probability measure on  $X \times C$ . Then  $P(\mathbf{x}, c)$  (precisely:  $P(\mathcal{H} = \mathbf{x}, \mathcal{C} = c)$ ) denotes the probability (1) to observe the vector  $\mathbf{x} \in X$  and (2) that  $\mathbf{x}$  belongs to class  $c \in C$ . Illustration:

Then  $P(\mathbf{x}, c)$  (precisely:  $P(\mathcal{H} = \mathbf{x}, \mathcal{C} = c)$ ) denotes the probability (1) to observe the vector  $\mathbf{x} \in X$  and (2) that  $\mathbf{x}$  belongs to class  $c \in C$ . Illustration:

ML:II-103 Basics

True Misclassification Rate: Probabilistic Foundation (continued)

Let X be a feature space, C a set of classes, and P a probability measure on  $X \times C$ . Then  $P(\mathbf{x}, c)$  (precisely:  $P(\mathcal{H} = \mathbf{x}, \mathcal{C} = c)$ ) denotes the probability (1) to observe the vector  $\mathbf{x} \in X$  and (2) that  $\mathbf{x}$  belongs to class  $c \in C$ . Illustration:

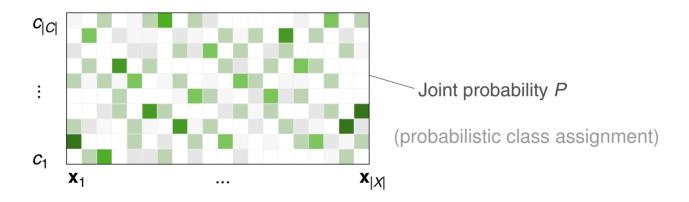

$$\underline{\textit{Err}^*(y)} = \sum_{\mathbf{x} \in X} \sum_{c \in C} P(\mathbf{x}, c) \cdot I(y(\mathbf{x}), c), \quad \text{with } I(y(\mathbf{x}), c) = \left\{ \begin{array}{l} 0 \text{ if } y(\mathbf{x}) = c \\ 1 \text{ otherwise} \end{array} \right.$$

ML:II-104 Basics ©STEIN/LETTMANN 2005-2019

True Misclassification Rate: Probabilistic Foundation (continued)

Let X be a feature space, C a set of classes, and P a probability measure on  $X \times C$ . Then  $P(\mathbf{x}, c)$  (precisely:  $P(\mathcal{H} = \mathbf{x}, \mathcal{C} = c)$ ) denotes the probability (1) to observe the vector  $\mathbf{x} \in X$  and (2) that  $\mathbf{x}$  belongs to class  $c \in C$ . Illustration:

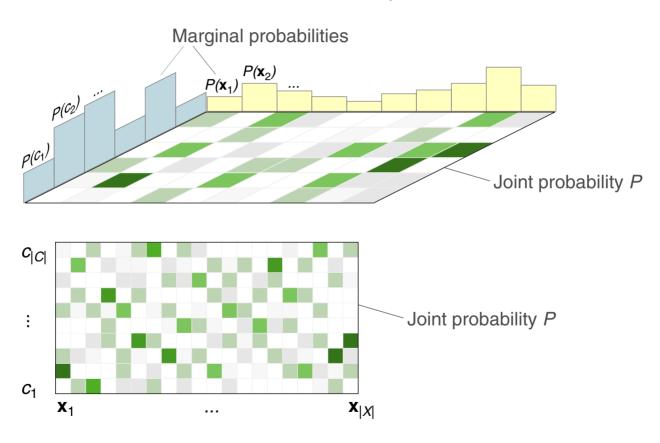

$$\operatorname{\mathit{Err}}^*(y) = \sum_{\mathbf{x} \in X} \sum_{c \in C} P(\mathbf{x}, c) \cdot I(y(\mathbf{x}), c), \quad \text{with } I(y(\mathbf{x}), c) = \left\{ \begin{array}{l} 0 & \text{if } y(\mathbf{x}) = c \\ 1 & \text{otherwise} \end{array} \right.$$

 $D = \{(\mathbf{x}_1, c_1), \dots, (\mathbf{x}_n, c_n)\} \subseteq X \times C$  is a set of examples whose elements are drawn independently and according to the same P.

- $\square$   $\mathcal{H}$  and  $\mathcal{C}$  are random variables with domains X and C respectively. In particular, X may not be restricted to contain a finite number of elements.
- f x is modeled as random variable,  ${\cal H}$ , to account for the fact that each observation process is governed by a probability distribution, rendering certain observations more likely than others. Note that in the definition of the <u>True Misclassification Rate</u> the set X is implicitly treated as uniformly distributed: each element in X contributes to the same amount to  $Err^*$ .
- The function  $c(\mathbf{x})$  is modeled as random variable, C, since in the real world the classification of a feature vector  $\mathbf{x}$  may not be deterministic but the result of a random (measuring) process. Keyword: label noise.
- Let A and B denote two events, e.g.,  $A = {}^{"}\mathcal{H} = \mathbf{x}"$  and  $B = {}^{"}\mathcal{C} = c"$ . Then the following expressions are syntactic variants, i.e., they are semantically equivalent: P(A, B), P(A and B),  $P(A \wedge B)$ .
- Also the sampling process is a stochastic process: The elements in D and  $D_{ts}$  are considered as random variables that are both independent of each other and identically distributed. This property of a set of random variables is abbreviated with "i.i.d." If the elements in D or  $D_{ts}$  are not chosen according to P, then  $Err(y, D_{ts})$  cannot be used as an estimation of  $Err^*(y)$ . Keyword: sample selection bias

True Misclassification Rate: Probabilistic Foundation (continued)

Illustration of the marginal probabilities  $P(c_i)$  and  $P(\mathbf{x}_j)$ :

- $P(\mathbf{x} \mid c_i)$  is the probability distribution of  $\mathcal{H}$  under class  $\mathcal{C} = c_i$ .  $P(\mathbf{x} \mid c_i)$  is also called "class-conditional *probability [density]* function".
  - In the illustration: the distribution of  $\mathbf{x}$  (consider a row) for a certain class c. Summation (integration) over the  $\mathbf{x} \in X$  yields the marginal probability  $P(c_i)$ .
- $P(c \mid \mathbf{x}_j)$  is the probability distribution of C under feature vector  $H = \mathbf{x}_j$ .  $P(c \mid \mathbf{x}_j)$  is also called "conditional *class probability* function".
  - In the illustration: the distribution of c (consider a column) for a certain feature vector  $\mathbf{x}$ . Summation over the  $c \in C$  yields the marginal probability  $P(\mathbf{x}_j)$ .
- $P(\mathbf{x}_j, c_i) = P(\mathbf{x}_j \mid c_i) \cdot P(c_i)$ , where  $P(c_i)$  is the a-priori probability for (observing) event  $c_i$ , and  $P(\mathbf{x}_j \mid c_i)$  is the probability for (observing) event  $\mathbf{x}_j$  given event  $c_i$ .
  - Likewise,  $P(\mathbf{x}_j, c_i) = P(c_i, \mathbf{x}_j) = P(c_i \mid \mathbf{x}_j) \cdot P(\mathbf{x}_j)$ , where  $P(\mathbf{x}_j)$  is the a-priori probability for (observing) event  $\mathbf{x}_j$ , and  $P(c_i \mid \mathbf{x}_j)$  is the probability for (observing) event  $c_i$  given event  $\mathbf{x}_j$ .
- □ Let both events  $\mathcal{H} = \mathbf{x}_j$  and  $\mathcal{C} = c_i$  have occurred already, and, let  $\mathbf{x}_j$  be known and  $c_i$  be unknown. Then,  $P(\mathbf{x}_i \mid c_i)$  is called *likelihood* (for event  $\mathbf{x}_i$  given event  $c_i$ ).

Training Error [True Misclassification Rate]

- $D = \{(\mathbf{x}_1, c(\mathbf{x}_1)), \dots, (\mathbf{x}_n, c(\mathbf{x}_n))\} \subseteq X \times C \text{ is a set of examples.}$
- $\Box$   $D_{tr} = D$  is the training set.
- $\neg y: X \to C$  is a classifier learned on the basis of  $D_{tr}$ .

Training error = misclassification rate with respect to  $D_{tr}$ :

$$Err(y, D_{tr}) = \frac{|\{(\mathbf{x}, c(\mathbf{x})) \in D_{tr} : y(\mathbf{x}) \neq c(\mathbf{x})\}|}{|D_{tr}|}$$

Training Error [True Misclassification Rate]

- $D = \{(\mathbf{x}_1, c(\mathbf{x}_1)), \dots, (\mathbf{x}_n, c(\mathbf{x}_n))\} \subseteq X \times C \text{ is a set of examples.}$
- $\Box$   $D_{tr} = D$  is the training set.
- $\neg y:X\to C$  is a classifier learned on the basis of  $D_{tr}$ .

Training error = misclassification rate with respect to  $D_{tr}$ :

$$Err(y, D_{tr}) = \frac{|\{(\mathbf{x}, c(\mathbf{x})) \in D_{tr} : y(\mathbf{x}) \neq c(\mathbf{x})\}|}{|D_{tr}|}$$

### Problems:

- $\Box$  *Err*(y,  $D_{tr}$ ) is based on examples that are also exploited to learn y.
- $\rightarrow$  *Err*( $y, D_{tr}$ ) quantifies memorization but not the generalization capability of y.
- $\rightarrow$   $Err(y, D_{tr})$  is an optimistic estimation, i.e., it is constantly lower compared to the error incurred when applying y in the wild.

2-Fold Cross-Validation (Holdout Estimation) [True Misclassification Rate]

- $D = \{(\mathbf{x}_1, c(\mathbf{x}_1)), \dots, (\mathbf{x}_n, c(\mathbf{x}_n))\} \subseteq X \times C \text{ is a set of examples.}$
- $\square$   $D_{tr} \subset D$  is the training set.
- $\neg y: X \to C$  is a classifier learned on the basis of  $D_{tr}$ .
- $D_{ts} \subset D$  with  $D_{ts} \cap D_{tr} = \emptyset$  is a test set.

Holdout estimation = misclassification rate with respect to  $D_{ts}$ :

$$Err(y, D_{ts}) = \frac{|\{(\mathbf{x}, c(\mathbf{x})) \in D_{ts} : y(\mathbf{x}) \neq c(\mathbf{x})\}|}{|D_{ts}|}$$

2-Fold Cross-Validation (Holdout Estimation) [True Misclassification Rate]

- $D = \{(\mathbf{x}_1, c(\mathbf{x}_1)), \dots, (\mathbf{x}_n, c(\mathbf{x}_n))\} \subseteq X \times C \text{ is a set of examples.}$
- $\square$   $D_{tr} \subset D$  is the training set.
- $\neg y:X\to C$  is a classifier learned on the basis of  $D_{tr}$ .
- $D_{ts} \subset D$  with  $D_{ts} \cap D_{tr} = \emptyset$  is a test set.

Holdout estimation = misclassification rate with respect to  $D_{ts}$ :

$$Err(y, D_{ts}) = \frac{|\{(\mathbf{x}, c(\mathbf{x})) \in D_{ts} : y(\mathbf{x}) \neq c(\mathbf{x})\}|}{|D_{ts}|}$$

### Requirements:

- $\Box$   $D_{tr}$  and  $D_{ts}$  must be governed by the same distribution.
- $\Box$   $D_{tr}$  and  $D_{ts}$  should have similar sizes.

- $\Box$  A typical value for splitting D into training set  $D_{tr}$  and test set  $D_{ts}$  is 2:1.
- $\Box$  When splitting D into  $D_{tr}$  and  $D_{ts}$  one has to ensure that the underlying distribution is maintained. Keywords: stratification, sample selection bias

k-Fold Cross-Validation [Holdout Estimation]

- $\neg$  Form k test sets by splitting D into disjoint sets  $D_1, \ldots, D_k$  of similar size.
- $\Box$  For  $i = 1, \ldots, k$  do:
  - 1.  $y_i: X \to C$  is a classifier learned on the basis of  $D \setminus D_i$

2. 
$$Err(y_i, D_i) = \frac{|\{(\mathbf{x}, c(\mathbf{x}) \in D_i : y_i(\mathbf{x}) \neq c(\mathbf{x})\}|}{|D_i|}$$

Cross-validated misclassification rate:

$$\textit{Err}_{cv}(y,D) = rac{1}{k} \sum_{i=1}^{k} \textit{Err}(y_i,D_i)$$

*n*-Fold Cross-Validation (Leave One Out)

### Special case with k = n:

 $\Box$  Determine the cross-validated misclassification rate for  $D \setminus D_i$  where

$$D_i = \{(\mathbf{x}_i, c(\mathbf{x}_i))\}, i \in \{1, \dots, n\}$$
.

*n*-Fold Cross-Validation (Leave One Out)

### Special case with k = n:

Determine the cross-validated misclassification rate for  $D \setminus D_i$  where  $D_i = \{(\mathbf{x}_i, c(\mathbf{x}_i))\}, i \in \{1, \dots, n\}$ .

### Problems:

- $\Box$  High computational effort if D is large.
- $\Box$  Singleton test sets ( $|D_i|=1$ ) are never stratified since they contain a single class only.

- $\Box$  For large k the set  $D \setminus D_i$  is of similar size as D. Hence  $\mathit{Err}(y_i, D_i)$  is close to  $\mathit{Err}(y, D)$ , where y is the classifier learned on the basis of the entire set D.
- $\Box$  *n*-fold cross-validation is a special case of exhaustive cross-validation methods, which learn and test on all possible ways to divide the original sample into a training and a validation set. [Wikipedia]

Bootstrapping [Holdout Estimation]

### Resampling the example set D:

- $\Box$  For  $j=1,\ldots,l$  do:
  - 1. Form training set  $D_i$  by drawing m examples from D with replacement.
  - 2.  $y_j: X \to C$  is a classifier learned on the basis of  $D_j$

3. 
$$Err(y_j, D \setminus D_j) = \frac{|\{(\mathbf{x}, c(\mathbf{x})) \in D \setminus D_j : y_j(\mathbf{x}) \neq c(\mathbf{x})\}|}{|D \setminus D_j|}$$

### Bootstrapped misclassification rate:

$$\textit{Err}_{bt}(y, D) = \frac{1}{l} \sum_{i=1}^{l} \textit{Err}(y_j, D \setminus D_j)$$

- □ Let |D| = n. The probability that an example is not considered is  $(1 1/n)^m$ . Hence, the probability that an example is considered at least once is  $1 (1 1/n)^m$ .
- If m gets closer to n, then  $1 (1 1/n)^m \approx 1 1/e \approx 0.632$ . I.e., each training set contains about 63.2% of the examples in D.
- The classifiers  $y_1, \ldots, y_l$  can be used in a combined fashion, called *ensemble*, where the class is determined by means of a majority decision:

$$y(\mathbf{x}) = \operatorname*{argmax}_{c \in C} |\{j \in \{1, \dots, l\} : y_j(\mathbf{x}) = c\}|$$

Misclassification Costs [Holdout Estimation]

Use of a cost measure for the misclassification of a feature vector  $\mathbf{x}$  in class c' instead of in class c:

$$cost(c' \mid c)$$
  $\begin{cases} \geq 0 & \text{if } c' \neq c \\ = 0 & \text{otherwise} \end{cases}$ 

Estimation of  $\mathit{Err}^*_{\mathit{cost}}(y)$  based on a sample  $D_{ts} \subseteq D$ :

$$\textit{Err}_{\textit{cost}}(y, D_{ts}) = \frac{1}{|D_{ts}|} \cdot \sum_{(\mathbf{x}, c(\mathbf{x})) \in D_{ts}} \textit{cost}(y(\mathbf{x}) \mid c(\mathbf{x}))$$

□ The misclassification rate *Err* is a special case of  $Err_{cost}$  with  $cost(c' \mid c) = 1$  for  $c' \neq c$ .
