### Questions:

- How many words are there?
- How do we count?

```
bank<sup>(1)</sup> (the financial institution),
bank<sup>(2)</sup> (land along the side of a river or lake),
banks<sup>(1)</sup>, banks<sup>(2)</sup>, ...
```

How often does each word occur?

### Questions:

- How many words are there?
- How do we count?

```
bank<sup>(1)</sup> (the financial institution),
bank<sup>(2)</sup> (land along the side of a river or lake),
banks<sup>(1)</sup>, banks<sup>(2)</sup>, . . .
```

How often does each word occur?

### **Experiment:**

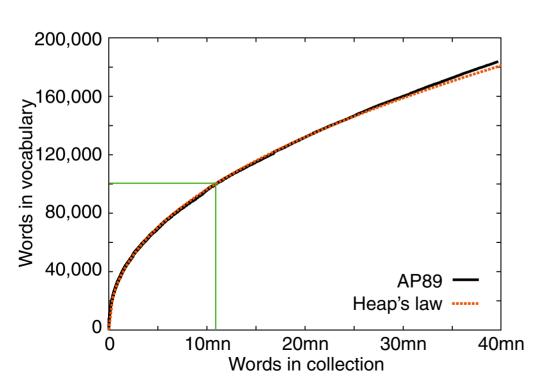

- Read a text left to right (beginning to end); make a tally of every new word seen.
- $\ \square$  *n* words seen in total, v(n) different words so far.
- $\Box$  How does the vocabulary V (set of distinct words) grow?  $\to$  Plot v(n).

Vocabulary Growth: Heaps' Law

The vocabulary V of a collection of documents grows with the collection. Vocabulary growth can be modeled with Heaps' Law:

$$|V| = k \cdot n^{\beta},$$

where n is the number of non-unique words, and k and  $\beta$  are collection parameters.

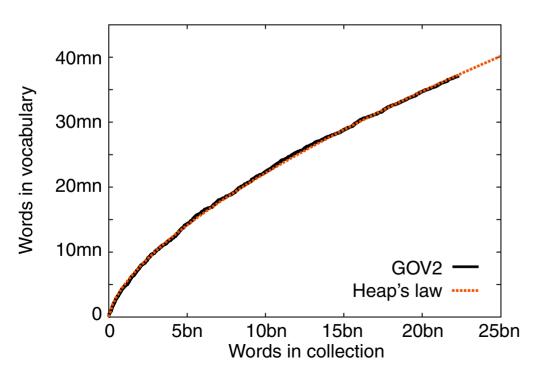

- □ Corpus: AP89
- $k = 62.95, \beta = 0.455$
- □ At 10,879,522 words: 100,151 predicted, 100,024 actual.
- ightharpoonup At < 1,000 words: poor predictions

Vocabulary Growth: Heaps' Law

The vocabulary V of a collection of documents grows with the collection. Vocabulary growth can be modeled with Heaps' Law:

$$|V| = k \cdot n^{\beta},$$

where n is the number of non-unique words, and k and  $\beta$  are collection parameters.

- □ Corpus: GOV2
- $k = 7.34, \beta = 0.648$
- Vocabulary continuously grows in large collections
- New words include spelling errors, invented words, code, other languages, email addresses, etc.

### Term Frequency: Zipf's Law

- □ The distribution of word frequencies is very *skewed*: Few words occur very frequently, many words hardly ever.
- □ For example, the two most common English words (the, of) make up about 10% of all word occurrences in text documents. In large text samples, about 50% of the unique words occur only once.

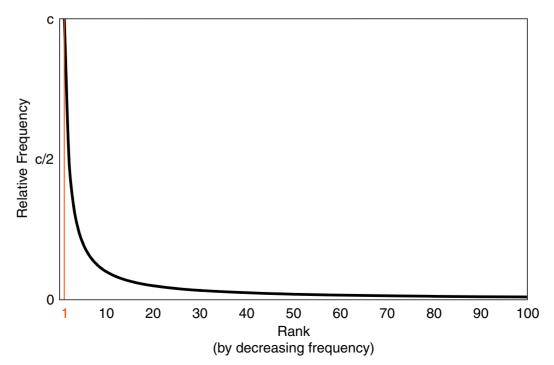

George Kingsley Zipf, an American linguist, was among the first to study the underlying statistical relationship between the frequency of a word and its rank in terms of its frequency, formulating what is known today as Zipf's law.

Term Frequency: Zipf's Law (continued)

The relative frequency P(w) of a word w in a sufficiently large text (collection) inversely correlates with its frequency  $\operatorname{rank} r(w)$  in a power law:

$$P(w) = \frac{c}{(r(w))^a} \qquad \Leftrightarrow \qquad P(w) \cdot r(w)^{\alpha} = c,$$

where c is a constant and the exponent a is language-dependent; often  $a \approx 1$ .

Term Frequency: Zipf's Law (continued)

Example: Top 50 most frequent words from AP89. Have a guess at c?

$\overline{r}$	$\overline{w}$	frequency	$P \cdot 100$	$P \cdot r$	$\overline{r}$	$\overline{w}$ 1	frequency	$P \cdot 100$	$P \cdot r$

25	but	140,880	0.35	0.089	50	people	68,988	0.17	0.087

### Remarks:

### □ Collection statistics for AP89:

Total documents	84,678
Total word occurrences	39,749,179
Vocabulary size	198,763
Words occurring > 1000 times	4,169
Words occurring once	70,064

Term Frequency: Zipf's Law (continued)

For relative frequencies, *c* can be estimated as follows:

$$1 = \sum_{i=1}^{n} P(w_i) = \sum_{i=1}^{n} \frac{c}{r(w_i)} = c \sum_{i=1}^{n} \frac{1}{r(w_i)} = c \cdot H_n, \quad \rightsquigarrow \quad c = \frac{1}{H_n} \approx \frac{1}{\ln(n)}$$

where n is the size |V| of the vocabulary V, and  $H_n$  is the n-th harmonic number.

Thus, the expected average number of occurrences of a word  $\boldsymbol{w}$  in a document  $\boldsymbol{d}$  of length  $\boldsymbol{m}$  is

$$m \cdot P(w)$$
,

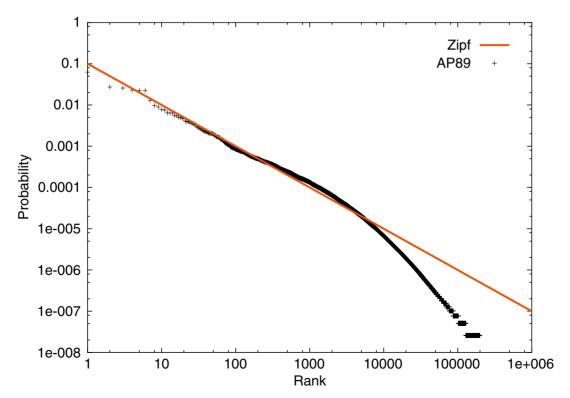

since P(w) can be interpreted as a term occurrence probability.

Term Frequency: Zipf's Law (continued)

By logarithmization a linear form is obtained, yielding a straight line in a plot:

$$\log(P(w)) \ = \ \log(c) - a \cdot \log(r(w))$$

### Example for AP89:

#### Remarks:

- As with all empirical laws, Zipf's law holds only approximately. While mid-range ranks of the frequency distribution fit quite well, this is less so for the lowest ranks and very high ranks (i.e., very infrequent words). The <u>Zipf-Mandelbrot law</u> is an extension of Zipf's law that provides for a better fit.
- Interestingly, this relation cannot only be observed for words and letters in human language texts or music score sheets, but for all kinds of natural symbol sequences (e.g., DNA). It is also true for randomly generated character sequences where one character is assigned the role of a blank space. [Li 1992]
- □ Independently of Zipf's law, a special case is <u>Benford's law</u>, which governs the frequency distribution of first digits in a number.

Term Frequency: Zipf's Law (continued)

The number of words in V with a given absolute frequency x can be estimated by

$$\frac{1}{x(x+1)}$$

#### Derivation:

Let  $r_x$  denote the lowest rank of a word with frequency x (i.e., the one with the largest rank "number"). Then the number of words with that frequency is derived as follows:

$$r_x - r_{x+1} = \frac{c_1}{p_x} - \frac{c_1}{p_{x+1}} = \frac{c_1 c_2}{x} - \frac{c_1 c_2}{x+1} = \frac{c_1 c_2}{x(x+1)},$$

where  $r_x \cdot p_x = c_1$ , and  $p_x = x/c_2$  its relative frequency, given the total number of non-unique words  $c_2$ . Its proportion of V is obtained by dividing by  $|V| = r_1 = c_1 c_2$ .

Term Frequency: Zipf's Law (continued)

The number of words in V with a given absolute frequency x can be estimated by

$$\frac{1}{x(x+1)}$$

### Derivation:

Let  $r_x$  denote the lowest rank of a word with frequency x (i.e., the one with the largest rank "number"). Then the number of words with that frequency is derived as follows:

$$r_x - r_{x+1} = \frac{c_1}{p_x} - \frac{c_1}{p_{x+1}} = \frac{c_1 c_2}{x} - \frac{c_1 c_2}{x+1} = \frac{c_1 c_2}{x(x+1)},$$

where  $r_x \cdot p_x = c_1$ , and  $p_x = x/c_2$  its relative frequency, given the total number of non-unique words  $c_2$ . Its proportion of V is obtained by dividing by  $|V| = r_1 = c_1 c_2$ .

#### Observations:

- $\Box$  Estimations are fairly accurate for small x.
- Roughly half of all words can be expected to be unique.

Estimating Result Set Size

tropical fish aquarium

Search

Web results

Page 1 of 3,880,000 results

The total number of results is estimated, since web search engines typically do not explore the entire indexed document collection to compute the first page of results returned, but only a subset.

### Approaches:

- Joint probability estimation
- Conditional probability estimation
- Initial result set-based estimation

### Remarks:

 $\Box$  Example data from the GOV2 collection (collection size |D| is 25,205,179):

Query	Document frequency
tropical	120,990
fish	1,131,855
aquarium	26,480
breeding	81,885
tropical fish	18,472
tropical aquarium	1,921
tropical breeding	5,510
fish aquarium	9,722
fish breeding	36,427
aquarium breeding	1,848
tropical fish aquarium	1,529
tropical fish breeding	3,629

Estimating Result Set Size: Joint Probability

Let  $P_{df}(w)$  denote the probability of w occurring at least once in a document:

$$P_{df}(w) = \frac{df(w)}{|D|},$$

where D denotes the document collection of size |D| and df(w) the number of documents in D containing w, called document frequency.

Estimating Result Set Size: Joint Probability

Let  $P_{df}(w)$  denote the probability of w occurring at least once in a document:

$$P_{df}(w) = \frac{df(w)}{|D|},$$

where D denotes the document collection of size |D| and df(w) the number of documents in D containing w, called document frequency.

The result set size df(q) of a query q of length |q| words can be estimated with

$$df(q) = |D| \cdot \prod_{i=1}^{|q|} P_{df}(w_i) = \frac{\prod_{i=1}^{|q|} df(w_i)}{|D|^{|q|-1}},$$

where  $w_i$  denotes the *i*-th word in q. This estimation presumes word independence.

Estimating Result Set Size: Joint Probability

Let  $P_{df}(w)$  denote the probability of w occurring at least once in a document:

$$P_{df}(w) = \frac{df(w)}{|D|},$$

where D denotes the document collection of size |D| and df(w) the number of documents in D containing w, called document frequency.

The result set size df(q) of a query q of length |q| words can be estimated with

$$df(q) = |D| \cdot \prod_{i=1}^{|q|} P_{df}(w_i) = \frac{\prod_{i=1}^{|q|} df(w_i)}{|D|^{|q|-1}},$$

where  $w_i$  denotes the *i*-th word in q. This estimation presumes word independence.

### Examples:

 $\Box$  df(tropical fish aquarium) = 5.71

 $\Box$  df(tropical fish breeding) = 17.65

actual: 1,529 documents

actual: 3.629 documents

Estimating Result Set Size: Conditional Probability

By exploiting word co-occurrence information, we can obtain better estimates with

$$P_{df}(q) = P_{df}(w_1 \cap w_2 \cap w_3) = P_{df}(w_1 \cap w_2) \cdot P_{df}(w_3 \mid w_1 \cap w_2),$$

where  $P_{df}(w_3 \mid w_1 \cap w_2) \approx P_{df}(w_3 \mid w_x) = \max\{P_{df}(w_3 \mid w_1), P_{df}(w_3 \mid w_2)\}$  and |q| = 3. Recall that  $P(A \mid B) = P(A \cap B)/P(B)$ . Hence

$$df(q) = |D| \cdot P_{df}(q) = \frac{df(w_1, w_2) \cdot df(w_x, w_3)}{df(w_x)}.$$

Estimating Result Set Size: Conditional Probability

By exploiting word co-occurrence information, we can obtain better estimates with

$$P_{df}(q) = P_{df}(w_1 \cap w_2 \cap w_3) = P_{df}(w_1 \cap w_2) \cdot P_{df}(w_3 \mid w_1 \cap w_2),$$

where  $P_{df}(w_3 \mid w_1 \cap w_2) \approx P_{df}(w_3 \mid w_x) = \max\{P_{df}(w_3 \mid w_1), P_{df}(w_3 \mid w_2)\}$  and |q| = 3. Recall that  $P(A \mid B) = P(A \cap B)/P(B)$ . Hence

$$df(q) = |D| \cdot P_{df}(q) = \frac{df(w_1, w_2) \cdot df(w_x, w_3)}{df(w_x)}.$$

- $\Box$  Queries of length |q|=2 need not be estimated, anymore.
- $\Box$  Queries of length |q|=3 are typically underestimated.
- $\Box$  Queries of length |q| > 3 still require estimations based on word independence, or storing higher-order co-occurrence information.

### Examples:

- $\Box$  df(tropical fish aquarium) = 293
- $\Box$  df(tropical fish breeding) = 841

actual: 1,529 documents

actual: 3,629 documents

Estimating Result Set Size: Initial Result Set-based Estimation

Let  $D' \subset D$  denote the documents initially scored for a query q. Then the size of the total result set in D can be estimated with

$$df(q) = |D_w| \cdot \frac{|D'_q|}{|D'|} = |D_w| \cdot \frac{|\{d \mid d \in D' \land q \in d\}|}{|D'|},$$

where w is the query term with the smallest subset  $D_w \subset D$  of documents that contain w, and  $D_q' \subset D'$  is the subset of the initially scored documents D' that contain all words of q.

This estimation presumes relevant documents are uniformly distributed across all documents in  $D_w$ . Why does it usually overestimate the result set size?

#### Examples:

- $\hfill \Box$  With  $D_{\hfill \mbox{\scriptsize aguarium}}=26,480,$  let |D'|=3,000, and  $|D'_q|=258$  :
- $\Box$  df(tropical fish aquarium) = 2,277

actual: 1,529 documents

- $\Box$  With  $D_{\texttt{breeding}} = 81,885$ , let |D'| = 3,000, and  $|D'_q| = 150$ :
- $\Box$  df(tropical fish breeding) = 4,094

actual: 3,629 documents

Estimating Result Set Size: Initial Result Set-based Estimation

Let  $D' \subset D$  denote the documents initially scored for a query q. Then the size of the total result set in D can be estimated with

$$df(q) = |D_w| \cdot \frac{|D_q'|}{|D'|} = |D_w| \cdot \frac{|\{d \mid d \in D' \land q \in d\}|}{|D'|},$$

where w is the query term with the smallest subset  $D_w \subset D$  of documents that contain w, and  $D_q' \subset D'$  is the subset of the initially scored documents D' that contain all words of q.

This estimation presumes relevant documents are uniformly distributed across all documents in  $D_w$ . Overestimations result from D' containing the most "important" documents indexed. As |D'| approaches  $|D_w|$ , estimations approach the true value.

### Examples:

- $\Box$  With  $D_{ ext{aguarium}}=26,480$ , let |D'|=6,000, and  $|D'_q|=402$ :
- $\Box$  df(tropical fish aquarium) = 1,774

- actual: 1,529 documents
- $\square$  With  $D_{\texttt{breeding}} = 81,885$ , let |D'| = 6,000, and  $|D'_q| = 276$ :
- $\Box$  df(tropical fish breeding) = 3,767

actual: 3,629 documents

Estimating Collection Size: Joint Probability-based

Most search engines are black boxes to outsiders, and many do not share the size of the document collection they index, so that estimating that size has become an important task, both for academia and industry.

Given a web search engine, the size |D| of the document collection D indexed can be estimated using two independently occurring words  $w_1$  and  $w_2$ :

$$P_{df}(w_1 \cap w_2) = P_{df}(w_1) \cdot P_{df}(w_2) \quad \rightsquigarrow \quad |D| = \frac{df(w_1) \cdot df(w_2)}{df(w_1, w_2)}.$$

Averaging over many word pairs improves the estimate.

#### Example for GOV2:

- $ext{d}f( ext{tropical}) = 120,990, \\ df( ext{lincoln}) = 771,326, ext{and} \\ df( ext{tropical, lincoln}) = 3018.$
- $\Box$  Then |D| = 30,922,045

actual: 25,205,179 documents

Estimating Collection Size: Proportionality [van den Bosch 2016] [worldwidewebsize.com]

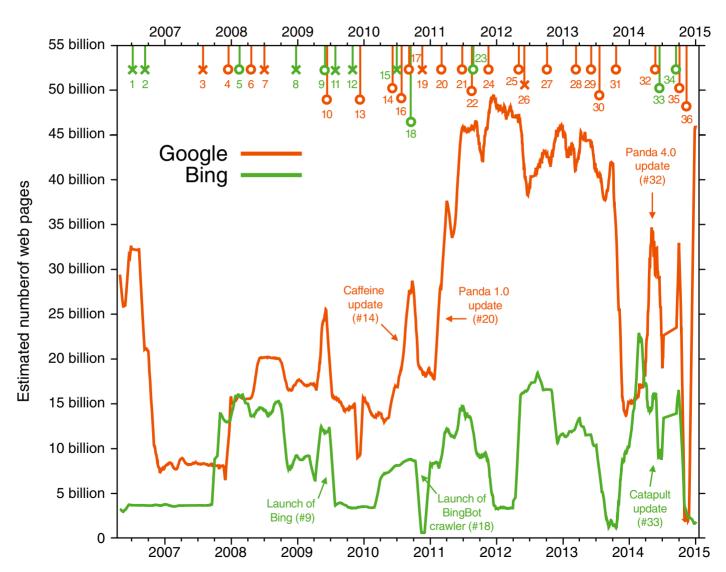

Given a web search engine, the size |D| of the document collection D indexed can be estimated when presuming proportionality to a different reference collection D':

$$P_{df}^{(D)}(w) = P_{df}^{(D')}(w) \quad \rightsquigarrow \quad |D| = \frac{df_D(w) \cdot |D'|}{df_{D'}(w)},$$

where  $df_D$  computes the document frequency for D.

Averaging over words of varying frequencies improves the estimate.

Estimating Collection Size: Proportionality [van den Bosch 2016] [worldwidewebsize.com]

#### Remarks:

- 1. [2006-07-04] MSN Search outage
- 2. [2006-09-11] Launch of (improvements to) Live Search
- 3. [2007-07-31] Update to supplemental results indexing
- 4. [2007-12-18] No more supplemental index; whole index is searched for every query
- 5. [2008-02-12] Crawler improvements for Live Search
- 6. [2008-04-11] Improved crawling of HTML forms
- 7. [2008-06-30] Improved Flash indexing
- 8. [2008-12-11] First experiments with MSNBot 2.0
- 9. [2009-05-28] Launch of Bing
- 10. [2009-06-18] Improved Flash indexing
- 11. [2009-07-31] Bing and Yahoo! team up on search
- 12. [2009-11-04] MSNBot 2.0
- 13. [2009-12-07] Updates to real-time search
- 14. [2010-06-08] Launch of new web indexing system Caffeine
- 15. [2010-06-28] Experiments with BingBot crawler
- 16. [2010-07-29] Improved Flash & AJAX indexing
- 17. [2010-08-31] Google indexes SVG
- 18. [2010-09-03] Launch of BingBot crawler
- 19. [2010-11-11] Improved Flash indexing
- 20. [2011-02-24] Panda Refresh (update to promote (English) high-quality sites more)

#### Remarks: (continued)

- 21. [2011-06-21] Panda 2.2
- 22. [2011-08-12] Panda (rolled out to all languages)
- 23. [2011-08-15] Gradual roll-out of Tiger indexing architecture
- 24. [2011-11-03] Panda (update, affects 35% of queries)
- 25. [2012-04-24] Penguin update (targeting Web spam, impacting around 3.1% of queries)
- 26. [2012-05-26] Penguin 2 update (impacting less than 0.1% of queries)
- 27. [2012-10-05] Penguin 3 update (impacting around 0.3% of queries)
- 28. [2013-03-12] Panda update
- 29. [2013-05-22] Penguin 4 (v2.0, impacting 2.3% of queries)
- 30. [2013-07-18] Panda update
- 31. [2013-10-04] Penguin 5 (v2.1, impacting around 1% of queries)
